Experiment No. 1

Analyze the Boston Housing dataset and apply appropriate Regression Technique

Date of Performance: 27-07-23

Date of Submission: 17-08-23

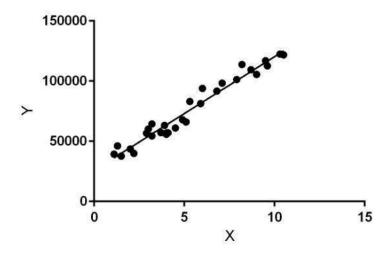

Department of Computer Engineering

Aim: Analyze the Boston Housing dataset and apply appropriate Regression Technique.

Objective: Ablility to perform various feature engineering tasks, apply linear regression on the given dataset and minimise the error.

Theory:

Linear Regression is a machine learning algorithm based on supervised learning. It performs a regression task. Regression models a target prediction value based on independent variables. It is mostly used for finding out the relationship between variables and forecasting. Different regression models differ based on – the kind of relationship between dependent and independent variables they are considering, and the number of independent variables getting used.

Linear regression performs the task to predict a dependent variable value (y) based on a given independent variable (x). So, this regression technique finds out a linear relationship between x (input) and y(output). Hence, the name is Linear Regression.

In the figure above, X (input) is the work experience and Y (output) is the salary of a person. The regression line is the best fit line for our model.

The Boston Housing Dataset

The Boston Housing Dataset is derived from information collected by the U.S. Census Service concerning housing in the area of Boston MA. The following describes the dataset columns:

CRIM - per capita crime rate by town

ZN - proportion of residential land zoned for lots over 25,000 sq.ft.

INDUS - proportion of non-retail business acres per town.

CHAS - Charles River dummy variable (1 if tract bounds river; 0 otherwise)

NOX - nitric oxides concentration (parts per 10 million)

RM - average number of rooms per dwelling

AGE - proportion of owner-occupied units built prior to 1940

DIS - weighted distances to five Boston employment centres

RAD - index of accessibility to radial highways

TAX - full-value property-tax rate per \$10,000

PTRATIO - pupil-teacher ratio by town

B - 1000(Bk - 0.63)² where Bk is the proportion of blacks by town

LSTAT - % lower status of the population

MEDV - Median value of owner-occupied homes in \$1000's

Code:

Conclusion:

Department of Computer Engineering

The selected set of features for estimating house prices includes several attributes that capture various aspects of the towns, which can influence the median home value. These attributes include CRIM, ZN, INDUS, CHAS, NOX, RM, AGE, DIS, RAD, TAX, PTRATIO, B, LSTAT.

Crime rate, proportion of residential land, nitric oxide concentration, average number of rooms, accessibility to highways, property-tax rate, etc., these factors influence home prices in different neighborhoods. The target variable, MEDV (Median Home Value), is the central focus of our prediction model; these features can predict the median value of homes.

The Mean Squared Error of 0.03112933398095344 indicates the average squared difference between predicted and actual house prices in the model. Comparing this value to the range of actual house prices determines if the model's predictions are accurate enough or not.
